- 1. (40 points) Suppose u is a unit vector in  $\mathbb{R}^n$ , so  $u^Tu=1$ . This problem is about the n by n symmetric matrix  $H=I-2u\,u^T$ .
  - (a) Show directly that  $H^2=I.$  Since  $H=H^T,$  we now know that H is not only symmetric but also \_\_\_\_\_\_.

Solution Explicitly, we find  $H^2 = (I - 2uu^T)^2 = I^2 - 4uu^T + 4uuu^T uu^T$  (2 points): since  $u^T u = 1$ ,  $H^2 = I$  (3 points). Since  $H = H^T$ , we also have  $H^T H = 1$ , implying that H is an orthogonal (or unitary) matrix.

- (b) One eigenvector of H is u itself. Find the corresponding eigenvalue. Solution Since  $Hu = (I - 2uu^T)u = u - 2uu^Tu = u - 2u = -u$ ,  $\lambda = -1$ .
- (c) If v is any vector perpendicular to u, show that v is an eigenvector of H and find the eigenvalue. With all these eigenvectors v, that eigenvalue must be repeated how many times? Is H diagonalizable? Why or why not?

Solution For any vector v orthogonal to u (i.e.  $u^Tv=0$ ), we have  $Hv=(I-2uu^T)v=v-2uu^Tv=v$ , so the associated  $\lambda$  is 1. The orthogonal complement to the space spanned by u has dimension n-1, so there is a basis of (n-1) orthonormal eigenvectors with this eigenvalue. Adding in the eigenvector u, we find that H is diagonalizable.

(d) Find the diagonal entries  $H_{11}$  and  $H_{ii}$  in terms of  $u_1, \ldots, u_n$ . Add up  $H_{11} + \ldots + H_{nn}$  and separately add up the eigenvalues of H.

Solution Since *i*th diagonal entry of  $uu^T$  is  $u_i^2$ , the *i* diagonal entry of H is  $H_{ii} = 1 - 2u_i^2$  (3 points). Summing these together gives  $\sum_{i=1}^n H_{ii} = n - 2\sum_{i=1}^n u_i^2 = n - 2$  (3 points). Adding up the eigenvalues of H also gives  $\sum \lambda_i = (1) - 1 + (n-1)(1) = n - 2$  (4 points).

- 2. (30 points) Suppose A is a positive definite symmetric n by n matrix.
  - (a) How do you know that  $A^{-1}$  is also positive definite? (We know  $A^{-1}$  is symmetric. I just had an e-mail from the International Monetary Fund with this question.)

Solution Since a matrix is positive-definite if and only if all its eigenvalues are positive (5 points), and since the eigenvalues of  $A^{-1}$  are simply the inverses of the eigenvalues of A,  $A^{-1}$  is also positive definite (the inverse of a positive number is positive) (5 points).

(b) Suppose Q is any **orthogonal** n by n matrix. How do you know that  $QAQ^T = QAQ^{-1}$  is positive definite? Write down which test you are using.

Solution Using the energy text  $(x^T A x > 0 \text{ for nonzero } x)$ , we find that  $x^T Q A Q^T x = (Q^T x)^T A (Q^T x) > 0$  for all nonzero x as well (since Q is invertible). Using the positive eigenvalue test, since A is similar to  $Q A Q^{-1}$  and similar matrices have the same eigenvalues,  $Q A Q^{-1}$  also has all positive eigenvalues. (5 points for test, 5 points for application)

(c) Show that the block matrix

$$B = \left[ \begin{array}{cc} A & A \\ A & A \end{array} \right]$$

is positive **semidefinite**. How do you know B is not positive definite?

Solution First, since B is singular, it cannot be positive definite (it has eigenvalues of 0). However, the pivots of B are the pivots of A in the first n rows followed by 0s in the remaining rows, so by the pivot test, B is still semi-definite. Similarly, the first n upper-left determinants of B are the same as those of A, while the remaining ones are 0s, giving another proof. Finally, given a nonzero vector

$$u = \left[ \begin{array}{c} x \\ y \end{array} \right]$$

where x and y are vectors in  $\mathbf{R}^n$ , one has  $u^T B u = (x+y)^T A (x+y)$  which is nonnegative (and zero when x+y=0).

## 3. (30 points) This question is about the matrix

$$A = \left[ \begin{array}{cc} 0 & -1 \\ 4 & 0 \end{array} \right]$$

.

(a) Find its eigenvalues and eigenvectors.

Write the vector  $u(0) = \begin{bmatrix} 2 \\ 0 \end{bmatrix}$  as a combination of those eigenvectors.

Solution Since  $\det(A - \lambda I) = \lambda^2 + 4$ , the eigenvalues are 2i, -2i (4 points). Two associated eigenvectors are  $\begin{bmatrix} 1 & -2i \end{bmatrix}^T$ , though there are many other choices (4 points). u(0) is just the sum of these two vectors (2 points).

(b) Solve the equation  $\frac{du}{dt} = Au$  starting with the same vector u(0) at time t = 0.

In other words: the solution u(t) is what combination of the eigenvectors of A?

Solution One simply adds in factors of  $e^{\lambda t}$  to each term, giving

$$u(t) = e^{2it} \begin{bmatrix} 1 \\ -2i \end{bmatrix} + e^{-2it} \begin{bmatrix} 1 \\ 2i \end{bmatrix}$$

- (c) Find the 3 matrices in the Singular Value Decomposition  $A = U \Sigma V^T$  in two steps.
  - -First, compute V and  $\Sigma$  using the matrix  $A^TA$ .
  - –Second, find the (orthonormal) columns of U.

Solution Note that  $A^TA = V\Sigma^T U^T U\Sigma V^T = V\Sigma^2 V^T$ , so the diagonal entries of  $\Sigma$  are simply the positive roots of the eigenvalues of

$$A^T A = \left[ \begin{array}{cc} 0 & 4 \\ -1 & 0 \end{array} \right] \left[ \begin{array}{cc} 0 & -1 \\ 4 & 0 \end{array} \right] = \left[ \begin{array}{cc} 16 & 0 \\ 0 & 1 \end{array} \right]$$

i.e.  $\sigma_1 = 4, \sigma_2 = 1$ . Since  $A^T A$  is already diagonal, V is the identity matrix. The columns of U should satisfy  $Au_1 = \sigma_1 v_1, Au_2 = \sigma_2 v_2$ : by inspection, one obtains

$$u_1 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, u_2 = \begin{bmatrix} -1 \\ 0 \end{bmatrix}, U = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$
